

Supplemental Methods:

Choice of species:

We selected 56 species of Malawi and Tanganyika cichlids for filming and UCE sequencing. We attempted to strike a balance between availability in the aquarium trade or via cichlid hobbyists, coverage of major tribes and ecotypes in each lake, and inclusion of potential independent transitions between suction feeding and biting.

Kinematics:

For filming, we housed between three and sixteen cichlids in 106L aquaria filtered with commercial air-driven sponge filters. We recorded kinematic sequences on a Fastec HiSpec 1 system (San Diego, CA, USA) at 2000 frames per second using a 120W halogen light to illuminate the tank from the side during recording. We introduced live prey (larval mosquitoes in the genus *Culex*) singly into the tank via pipette and obtained between eight and twenty kinematic sequences per individual. After each feeding trial, we placed a ruler in the same focal plane for scale. We waited at least 24 hours before using the same individual in another feeding trial. After filming, we euthanized fish with an overdose of MS-222. We then removed fin or muscle tissue for DNA extraction, library preparation, and UCE sequencing (described below), and we stored tissues in 95% EtOH at -20 C. We used one individual per species for UCE sequencing (below).

Digitizing:

From each set of videos for a given individual, we chose one sequence in which the predator appeared to be completely lateral with respect to the camera and striking with high effort. High effort strikes were identified via comparisons of mouth opening to all other kinematic sequences for that individual. We always captured images of the plateau phase (*sensu* 42) at the point immediately preceding jaw closing. From these sequences we isolated a pair of images, one at the onset of the strike before the jaws had begun to open and the other with the mouth fully opened.

We then digitized a series of four landmarks (Figure 2) on the two bones of the upper jaw, the premaxilla and maxilla, using the 'tpsDig' and 'tpsUtil' morphometrics software [46]. This set of landmarks was digitized on both the closed and the open mouth frames from each feeding sequence. We digitized the distal tip of the arm of the maxilla(landmark 1), the joint between the articular and the quadrate(landmark 2), the anterior-most tip of the premaxilla(landmark 3), and the proximal tip of the maxilla(landmark 4).

In order to capture the amount of shape change that occurred between the closed and the open mouth, we used the Procrustes distance, a common measure of shape difference. We calculated kinesis of the premaxilla, maxilla, and the lower jaw separately, using a series of three coordinates, one mobile and two fixed (landmarks 1 and 2). For our mobile landmark, we

used landmark 3 for premaxillary kinesis and landmark 4 for maxillary kinesis. We calculated the Procrustes distance from each open-closed pair of images per individual using the 'geomorph' package in R [47]. We then calculated species means by averaging the Procrustes distance of all individuals of a given species.

DNA Extraction and Library Preparation:

We extracted DNA from 56 specimen tissues stored in ethanol by cutting 10-20 mg chunks from each tissue using individually wrapped razor blades and following the Qiagen DNeasy protocol. We modified the protocol by eluting DNA from the column membrane using 65 μ L of warm (50-55 $^{\circ}$ C) Buffer AE. Following elution, we quantified DNA using a Qubit fluorometer by combining 2 μ L eluate with 198 μ L quantification reagent and following the Qubit quantification protocol. We extracted an average of 91.2 ng DNA (95 CI: 31.8) from individual cichlid tissue samples (Table S3). Following extraction and quantification, we determined the quality of DNA extracts by visualizing 50-100 ng of each extract by electrophoresis through 1.5% (w/v) agarose gel in TBE. We then prepared 100 μ L aliquots (10 ng/ μ L) of each sample for sonication, and we sheared each sample to 300-600 bp in length using 5-10 cycles of sonication (High; 30 s on; 90 s off) on a BioRuptor (Diagenode, Inc.).

To collect sequence data from UCEs, we followed modified versions (available from <http://ultraconserved.org>) of the enrichment approach initially described in [25-26] for library preparation (v1.10), target enrichment (v1.5), and post-enrichment recovery (v2.4). Briefly, we input sheared DNA to a "with-bead" library preparation process using commercial library preparation reagents (Kapa Biosystems) and a generic SPRI substitute ((Rohland & Reich 2012); hereafter SPRI). During adapter ligation, we substituted a custom-designed set of adapters that allows dual-indexing during the subsequent PCR amplification phase. Following universal adapter ligation, we amplified 50% of the library volume (~15 μ L) using a reaction mix of 25 μ L HiFi HotStart ReadyMix polymerase (Kapa Biosystems), 5 μ L of dual-indexed primer mix (5 μ M each), and 5 μ L double-distilled water (ddH₂O) using the following thermal protocol: 98 C for 45s; 10-12 cycles of 98 C for 15s, 60 C for 30s, 72 C for 60s; and a final extension of 72 C for 5m. We purified resulting reactions using 1.8X SPRI and rehydrated libraries in 33 μ L ddH₂O. We quantified 2 μ L of each library using a Qubit fluorometer. Following library preparation, PCR amplification, and purification, libraries contained an average of 49.7 DNA (95 CI: 1.2) in 33 μ L 10 mM Tris-HCl. We selected samples for grouping based on taxonomic similarity, and we combined 62.5 ng DNA from each sample into pools of eight libraries at equimolar ratios (500 ng each pool). The final concentration of each pool was 147 ng/ μ L.

Library Enrichment and Sequencing:

We enriched libraries for UCE targets following the protocol described above (v1.5) with the following reagents: (1) 100 ng MYcroarray MYBaits UCE Capture Kit baits; (2) 500 ng blocking oligos designed against our custom, dual sequence indexes; (3) 500 ng of commercially available chicken Cot-1 DNA (Applied Genetics Laboratories, Inc.); and (4) 1% SDS (versus 10% SDS). Previous tests [48] have suggested the organismal source of Cot-1 DNA is not

critical to enrichment success. We ran the hybridization reaction for 24 hours at 65 C. Following hybridization we bound all pools to streptavidin-coated beads (MyOne C1, Life Technologies, Inc.) and washed bound libraries according to the protocol. Following enrichment, we removed the final aliquot of wash buffer and allowed samples to dry for five minutes while sitting in a magnet stand. We removed residual buffer, added 30 μ L ddH₂O to each sample, and then proceeded directly to PCR recovery while the enriched libraries were still bound to streptavidin beads. We combined 15 μ L of streptavidin bead-bound, enriched library in water with 25 μ L HiFi HotStart ReadyMix polymerase (Kapa Biosystems), 5 μ L of Illumina TruSeq primer mix (5 μ M each), and 5 μ L of ddH₂O. We performed PCR recovery of each library using the following thermal profile: 98 C for 45s; 16 cycles of 98 C for 15s, 60 C for 30s, 72 C for 60s; and a final extension of 72 C for 5m. We purified resulting reactions using 1.0X SPRI, and we re-hydrated enriched pools in 33 μ L ddH₂O. We quantified 2 μ L of each enriched pool using a Qubit fluorometer, as described above. Following enrichment, PCR recovery, and purification, enriched pools contained approximately 34.0 ng DNA (95 CI: 4.6).

Prior to sequencing, we diluted PCR-recovered, enriched pools to 2.5 ng/ μ L, determined the fragment size distribution of each enriched pool using a Bioanalyzer (Agilent Technologies, Inc.), qPCR-quantified each pool using a commercial library quantification kit (Kapa Biosystems), and adjusted estimated library concentrations based on our qPCR results and the mean fragment size of each pool. We created an equimolar sample of all pools at 10 nM concentration for sequencing, and we sequenced the 10 nM sample of pooled libraries using approximately $\frac{1}{3}$ of an Illumina NextSeq PE150 run (Georgia Genomics Facility). We filled the remainder of the NextSeq run with samples having sequence tags at both 5' and 3' ends of the library construct that were completely different from any tags we applied to our cichlid samples.

Analysis of UCE data:

We converted BCL data to FASTQ data using `bcl2fastq2` (v02.14.01.07, Illumina Inc.), and we merged read data for each sample from the four NextSeq lanes into two FASTQ files representing Read 1 and Read 2 (`merge_next_seq_gzip_files.py` in the PHYLUCE package: <https://github.com/faircloth-lab/phyluce/>). Sequencing produced an average of 2,116,046 million reads (95 CI: 104,351; Table S4) per sample. We trimmed FASTQ data for adapter contamination and low-quality bases using a parallel wrapper (<https://github.com/faircloth-lab/illumiprocessor>) around Trimmomatic (Bolger et al. 2014). Following read trimming, we computed summary statistics on the data using `get_fastq_stats.py` from the PHYLUCE package, and trimmed reads averaged 139 bp in length (95 CI: 0.5; Table S4). We assembled the read data into contigs (Table S5) using a parallel wrapper around Trinity [version `trinityrnaseq-r2013-02-25`; `assemblo_trinity.py`], and we computed coverage across assembled contigs using a program (`get_trinity_coverage.py`) that re-aligns the trimmed sequence reads to each set of assembled contigs using BWA-MEM (Li 2013), cleans the resulting BAM files using PICARD (version 1.99; <http://picard.sourceforge.net/>), adds read-group (RG) information to each library using PICARD, indexes the resulting BAM file using SAMTOOLS, and calculates coverage at each base of each assembled contig using GATK [version 2.7.2. Trinity assembly of reads

produced an average of 22,100 contigs (95 CI: 1,484) of 338 bp in length (95 CI: 4.7; Supp Table BCF3).

To identify assembled contigs representing enriched UCE loci from each species, we aligned species-specific contig assemblies from both sequence assembly programs to a FASTA file of all enrichment baits using `match_contigs_to_loci.py`. We enriched an average of 1,040 unique UCE loci (Table S6) from each sample (95 CI: 2.7) having an average length of 668 bp (95 CI: 12.9), an average coverage of 39X (95 CI: 1.7). The mean percentage of reads-on-target was 34.1 (95 CI: 1.1).

We created a file containing the names of 56 enriched taxa from which we collected data (Table S3), as well as the name of a genome-enabled cichlid that we used as an outgroup (*Oreochromis niloticus*) and from which we extracted the same UCE loci *in silico*, and we input this list to an additional program (`get_match_counts.py`) that queries the relational database created by matching baits to assembled contigs, as well as the relational database containing UCE match data for genome-enabled taxa, to generate a list of UCE loci shared among all taxa. We input the list of loci generated by this program to an additional program (`get_fastas_from_match_counts.py`) to create a monolithic FASTA file containing all UCE sequence data for all taxa. We aligned all data in the monolithic FASTA file using a parallel wrapper (`seqcap_align_2.py`) around MAFFT, with the built-in trimming option of the wrapper turned off and FASTA output turned on. Following alignment, we trimmed each fasta alignment using a parallel wrapper (`get_gblocks_trimmed_alignments_from_untrimmed.py`) around GBLOCKS (trimming parameters `--b1=0.5; --b4=8`) which also converted resulting alignments to NEXUS format, and we removed the locus names from all alignments (`remove_locus_name_from_nexus_lines.py`).

Following UCE identification, alignment, and alignment trimming steps, we created two data sets by selecting two subsets of alignments (`get_only_loci_with_min_taxa.py`) that were 95% (54 of 56 taxa have data present in each alignment) and 75% complete (42 of 56 taxa have data present in each alignment). We generated alignment statistics across each subset of data, and we computed the number of informative sites across all alignments in each subset using `get_align_summary_data.py` and `get_informative_sites.py`. The 95% complete data set contained 939 loci, each containing a mean of 56.4 (95 CI: 0.05) taxa. After MAFFT alignment and GBLOCKS trimming, the average locus length in the 95% data set was 549.9 bp (95 CI: 6.23) and the concatenated supermatrix was 516,305 characters in length; contained 11,508 informative sites; and contained 55,503 site patterns. The 75% complete data set contained 1,043 loci, each having a mean of 55.8 (95 CI: 0.1) taxa. After MAFFT alignment and GBLOCKS trimming, the average locus length in the 75% data set was 541.4 bp (95 CI: 6.2) and the concatenated supermatrix was 564,686 characters in length; contained 13,012 parsimony informative sites; and contained 62,897 site patterns.

Phylogenetic analyses:

We concatenated each resulting data set into a PHYLIP-formatted supermatrix (format_nexus_files_for_raxml.py). We constructed an input file for PartitionFinder [49], which we used to partition each data set using the iterative kmeans clustering algorithm [50]; RAxML; and model selection by Bayesian Information Criterion. Following partitioning, we conducted the analyses we describe for each data set (95% and 75% complete) and each partitioning scheme (partitioned and unpartitioned).

We used the RAxML 8.0.19 [29] PTHREADS binary with the GTRGAMMA site rate substitution model on single, 16 CPU, 32 GB RAM nodes (mike.hpc.lsu.edu) to conduct 20 maximum-likelihood (ML) searches for the phylogenetic tree that best fit the data. Following the best tree search, we used RAxML to generate non-parametric bootstrap replicates using the autoMRE option, which runs bootstrapping until convergence of the bootstrap replicates. Following the best tree and bootstrap replicate analyses, we reconciled the best fitting ML tree with the bootstrap replicates. We also used the MPI version of ExaBayes 1.4.1 [28] on four, 16 CPU, 32 GB RAM nodes (mike.hpc.lsu.edu) to conduct four independent runs of 1-2 M iterations each for each data set (four independent runs; burn-in: 25%; thinning = 500). We used three heated chains to sample the posterior distribution the partitioned data analyses, because, following visual inspection of traces from preliminary runs, it appeared some runs were becoming stuck in local optima. We assessed runs for convergence using visualizations of the potential scale reduction factors and the standard deviation of the split frequencies output by the *postProcParams* and *sdsf* programs from the ExaBayes package. We also visually examined traces and ESS values for estimated parameters using Tracer [51]. We created a consensus tree from the independent runs using the *consense* program from the ExaBayes package (Figure S1, Figure S2).

The RAxML bootstrap replicate runs of all four data sets converged after 300 replicates. Bayesian analyses of the unpartitioned, 95% complete data set reached convergence (ADSF 0.001%; average PSRF = 1.0 ; ± 95 CI PSRF = 0.0003; average ESS = 4774.9; ± 95 CI ESS=938.5) after 2 million iterations, while Bayesian analysis of the partitioned 95% complete data set (ADSF 1.2%; average PSRF = 1.0 ; ± 95 CI PSRF = 0.001; average ESS = 4646.3; ± 95 CI ESS=223.0) reached convergence after 1 million iterations. Bayesian analyses of the unpartitioned, 75% complete data set reached convergence (ADSF 0.003%; average PSRF = 1.0 ; ± 95 CI PSRF = 0.0003; average ESS = 3428.7; ± 95 CI ESS=631.5) after 1 million iterations, and Bayesian analysis of the partitioned 75% complete data set (ADSF 0.2%; average PSRF = 1.0 ; ± 95 CI PSRF = 0.0001; average ESS = 4792.8; ± 95 CI ESS=148.7) reached convergence after 1 million iterations.

Converting trees to chronograms:

Prior to our phylogenetic ANOVAs (below), we used the 'chronoPL' function in R to convert our trees into chronograms using penalized likelihood. We set one calibration point at the split between *Bathybates minor* and the rest of the East African clade, using soft bounds of 9-12 million years, the generally accepted age of the lake. [45,52-53].

Figure S1. Consensus tree from our 95% unpartitioned ExaBayes analysis. Nodal values indicate posterior probabilities.

Figure S2. Consensus tree from our 75% unpartitioned ExaBayes analysis. Nodal values indicate posterior probabilities.

Identifying transitions in feeding mode:

To determine which species in our analyses were primarily biting taxa, we adopted two methodologies (Table S2). In the “strict” analysis, only herbivores and insect pickers in the rocky habitat, which feed by biting rocky surfaces, algal filaments, or freshwater sponges, were counted as biters, as this feeding mode is not known to be possible with suction feeding. We also included a molluscivorous species (*Chilotilapia rhoadesii*) known to crush snails directly with its oral jaws [16]. In the “loose” analyses, we also included two piscivorous species (*Rhamphochromis longiceps* and *Bathybates minor*) with greatly enlarged teeth on the premaxilla and dentary. These enlarged teeth suggest these two species function as “ram-biters” that overtake prey via body ram and impale prey on the oral jaw teeth. We also added two herbivorous and planktivorous species in the genus *Ophthalmotilapia* known to bite algae in the rocky habitat.

We then used stochastic character mapping in the R package ‘phytools’ [32] to map how many transitions between biting and suction feeder occurred in Tanganyika and Malawi. We split our phylogeny into Tanganyikan or Malawi species and simulated 1,000 stochastic character mappings for feeding mode based on the observed rate matrix for both the “strict” and “loose” designations with all rates allowed to differ, then recorded how many transitions occurred in each lake (Table S7). For all simulations, the minimum number of transitions was always greater than one, indicating that multiple feeding mode transitions occurred in each lake

radiation. Malawi averaged 5-6 transitions and Tanganyika averaged 7-13 across our set of RaxML/ExaBayes, 75%/95%, and unpartitioned/partitioned trees.

Comparative analysis of jaw kinesis with respect to feeding mode:

We performed phylogenetic ANOVAs on all consensus trees (75%/95%, RaxML/exaBayes, non-ultrametrized and ultrametrized) using 10,000 Brownian motion simulations with the 'aov.phylo' function in the geiger' package in R [54]. We analyzed both premaxillary kinesis and maxillary kinesis with respect to feeding mode, and used both the "strict" and "loose" designations for feeding mode. Regardless of the phylogenetic reconstruction used, (Table S8), biting taxa exhibited less premaxillary and maxillary jaw kinesis than suction feeding taxa.

Table S1. Species in the study

Species name	Number of individuals filmed
<i>Aristochromis christyi</i>	2
<i>Astatotilapia burtoni</i>	1
<i>Aulonocara stuartgranti</i>	1
<i>Bathybates minor</i>	1
<i>Chalinochromis brichardi</i>	1
<i>Cheilochromis euchilus</i>	1
<i>Chilotilapia rhoadesii</i>	1
<i>Cyprichromis pavo</i>	1
<i>Ectodus descampsii</i>	1
<i>Eretmodus cyanostictus</i>	1
<i>Fossorochromis rostratus</i>	1
<i>Gnathochromis permaxillaris</i>	1
<i>Haplotaxodon microlepis</i>	1
<i>Julidochromis dickfeldi</i>	1
<i>Labeotropheus fuelleborni</i>	1
<i>Labeotropheus trewavasae</i>	2
<i>Lamprologus callipterus</i>	3
<i>Lamprologus fasciatus</i>	2
<i>Lepidiolamprologus attenuatus</i>	2
<i>Lepidiolamprologus boulengeri</i>	2
<i>Lepidiolamprologus hecqui</i>	1
<i>Lepidiolamprologus lemairii</i>	2
<i>Lepidiolamprologus</i> sp. "meeli kipili"	3
<i>Limnochromis auritus</i>	2
<i>Melanochromis auratus</i>	1
<i>Melanochromis kaskazini</i>	1
<i>Neolamprologus cylindricus</i>	1
<i>Neolamprologus furcifer</i>	2
<i>Neolamprologus helianthus</i>	2
<i>Neolamprologus longicaudata</i>	4
<i>Neolamprologus leleupi</i>	5
<i>Neolamprologus modestus</i>	1
<i>Neolamprologus nigriventris</i>	1
<i>Neolamprologus obscurus</i>	3
<i>Neolamprologus olivaceous</i>	1
<i>Neolamprologus prochilus</i>	5
<i>Neolamprologus pulcher</i>	2
<i>Neolamprologus savoryi</i>	3
<i>Neolamprologus sexfasciatus</i>	2
<i>Neolamprologus tetracanthus</i>	2
<i>Neolamprologus walteri</i>	1
<i>Nimbochromis polystigma</i>	1

<i>Ophthalmotilapia boops</i>	1
<i>Ophthalmotilapia nasuta</i>	3
<i>Otopharynx lithobates</i>	1
<i>Placidochromis electra</i>	1
<i>Placidochromis milomo</i>	2
<i>Pseudotropheus crabro</i>	1
<i>Pseudotropheus flavus</i>	1
<i>Rhamphochromis longiceps</i>	1
<i>Simochromis babaulti</i>	1
<i>Telmatochromis dhonti</i>	2
<i>Telmatochromis</i> sp. "dhonti yellow"	2
<i>Telmatochromis temporalis</i>	1
<i>Trematochromis benthicola</i>	2
<i>Variabilichromis moorii</i>	3

Table S2. Biting species in two categories

Strict:	Specialization
<i>Chalinochromis brichardi</i>	Sponge-eater, algae-eater, insect picker [55]
<i>Chilotilapia rhoadesii</i>	Snail-eater, oral crusher [16,34]
<i>Eretmodus cyanostictus</i>	Algae-eater [55-57]
<i>Julidochromis dickfeldi</i>	Sponge-eater and insect picker[55]
<i>Labeotropheus fuelleborni</i>	Algae-eater [58]
<i>Labeotropheus trewavasae</i>	Algae-eater [34]
<i>Melanochromis auratus</i>	Algae-eater [58]
<i>Pseudotropheus crabro</i>	Parasite-eater [59]
<i>Pseudotropheus flavus</i>	Algae-eater [60]
<i>Simochromis babaulti</i>	Algae-eater [55]
<i>Telmatochromis temporalis</i>	Algae-eater [55-57]
<i>Variabilichromis moorii</i>	Algae-eater [55,57]
Loose:	
<i>Bathybates minor</i>	Ram-biting fish-eater [55], this study
<i>Rhamphochromis longiceps</i>	Ram-biting fish-eater [55], this study
<i>Ophthalmotilapia boops</i>	Algae-eater,plankton-eater [55]
<i>Ophthalmotilapia nasuta</i>	Algae-eater,plankton-eater [55-56]

Table S3. Species, location of sample collections/date of collection, identification number, processing identification number during UCE enrichment, DNA extracted, library concentration prior to PCR amplification, library concentration following PCR amplification.

Species	Location/Date Obtained	ID Number	Processing ID	DNA (ng/ul)	Pre-PCR (ng/ul)	Post-PCR (ng/ul)
